Description

Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the latin properties of the design.

Usage

augmentLHS(lhs, m = 1)

Arguments

lhs
The Latin Hypercube Design to which points are to be added. Contains an existing latin hypercube design with a number of rows equal to the points in the design (simulations) and a number of columns equal to the number of variables (parameters). The values of each cell must be between 0 and 1 and uniformly distributed

m
The number of additional points to add to matrix lhs

Details

Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the latin properties of the design. Augmentation is performed in a random manner.

The algorithm used by this function has the following steps. First, create a new matrix to hold the candidate points after the design has been re-partitioned into \((n + m)^2\) cells, where \(n\) is number of points in the original lhs matrix. Then randomly sweep through each column \((1\ldots k)\) in the repartitioned design to find the missing cells. For each column (variable), randomly search for an empty row, generate a random value that fits in that row, record the value in the new matrix. The new matrix can contain more filled cells than \(m\) unless \(m = 2n\), in which case the new matrix will contain exactly \(m\) filled cells. Finally, keep only the first \(m\) rows of the new matrix. It is guaranteed
to have \( m \) full rows in the new matrix. The deleted rows are partially full. The additional candidate points are selected randomly due to the random search for empty cells.

**Value**

An \( n \) by \( k \) Latin Hypercube Sample matrix with values uniformly distributed on \([0,1]\)

**Author(s)**

Rob Carnell

set.seed(1234)
a <- randomLHS(4,3)
b <- augmentLHS(a, 2)
```

---

**createAddelKemp**

Create an orthogonal array using the Addelman-Kempthorne algorithm.

**Description**

The addelkemp program produces \( OA(2q^2, k, q, 2) \), \( k \leq 2q+1 \), for odd prime powers \( q \).

**Usage**

```r
createAddelKemp(q, ncol, bRandom = TRUE)
```

**Arguments**

- \( q \) the number of symbols in the array
- \( ncol \) number of parameters or columns
- \( bRandom \) should the array be randomized
createAddelKemp3

Details

From Owen: An orthogonal array A is a matrix of n rows, k columns with every element being one of q symbols 0,...,q-1. The array has strength t if, in every n by t submatrix, the q^t possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted lambda. Clearly, lambda*q^t=n. The notation for such an array is OA( n,k,q,t ).

Value

an orthogonal array

References

See Also

Other methods to create orthogonal arrays [createBoseBush()], [createBose()], [createAddelKemp3()], [createAddelKempN()], [createBusht()], [createBoseBushl()]

Examples

A <- createAddelKemp(3, 3, TRUE)
B <- createAddelKemp(3, 5, FALSE)

createAddelKemp3

Create an orthogonal array using the Addelman-Kempthorne algorithm with 2q^3 rows.

Description

The addelkemp3 program produces OA( 2+q^3,k,q,2 ), k <= 2q^2+2q+1, for prime powers q. q may be an odd prime power, or q may be 2 or 4.

Usage

createAddelKemp3(q, ncol, bRandom = TRUE)

Arguments

q the number of symbols in the array
ncol number of parameters or columns
bRandom should the array be randomized
createAddelKempN

Details

From Owen: An orthogonal array $A$ is a matrix of $n$ rows, $k$ columns with every element being one of $q$ symbols $0, \ldots, q-1$. The array has strength $t$ if, in every $n$ by $t$ submatrix, the $q^t$ possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted $\lambda$. Clearly, $\lambda q^t = n$. The notation for such an array is $\text{OA}(n, k, q, t)$.

Value

an orthogonal array

Examples

A <- createAddelKemp3(3, 3, TRUE)
B <- createAddelKemp3(3, 5, FALSE)

createAddelKempN

Create an orthogonal array using the Addelman-Kempthorne algorithm with alternate strength with $2q^n$ rows.

Description

The addelkempn program produces $\text{OA}(2q^n, k, q, 2)$, $k \leq 2(q^n - 1)/(q-1)-1$, for prime powers $q$. $q$ may be an odd prime power, or $q$ may be 2 or 4.

Usage

createAddelKempN(q, ncol, exponent, bRandom = TRUE)

Arguments

q          the number of symbols in the array
ncol       number of parameters or columns
exponent   the exponent on $q$
bRandom    should the array be randomized
createBose

Details
From Owen: An orthogonal array \( A \) is a matrix of \( n \) rows, \( k \) columns with every element being one of \( q \) symbols \( 0, \ldots, q-1 \). The array has strength \( t \) if, in every \( n \) by \( t \) submatrix, the \( q^t \) possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted \( \lambda \). Clearly, \( \lambda q^t = n \). The notation for such an array is \( OA(n, k, q, t) \).

Value
an orthogonal array

Examples
A <- createAddelKempN(3, 4, 3, TRUE)
B <- createAddelKempN(3, 4, 4, TRUE)

--

createBose

Create an orthogonal array using the Bose algorithm.

Description
The bose program produces \( OA(q^2, k, q, 2) \), \( k \leq q+1 \) for prime powers \( q \).

Usage
createBose(q, ncol, bRandom = TRUE)

Arguments
q the number of symbols in the array
ncol number of parameters or columns
bRandom should the array be randomized

Details
From Owen: An orthogonal array \( A \) is a matrix of \( n \) rows, \( k \) columns with every element being one of \( q \) symbols \( 0, \ldots, q-1 \). The array has strength \( t \) if, in every \( n \) by \( t \) submatrix, the \( q^t \) possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted \( \lambda \). Clearly, \( \lambda q^t = n \). The notation for such an array is \( OA(n, k, q, t) \).

Value
an orthogonal array
createBoseBush

[createAddelKemp3()], [createAddelKempN()], [createBusht()], [createBoseBushl()]

Examples

A <- createBose(3, 3, FALSE)
B <- createBose(5, 4, TRUE)

createBoseBush

Create an orthogonal array using the Bose-Bush algorithm.

Description

The bosebush program produces OA( 2q^2,k,q,2 ), k <= 2q+1, for powers of 2, q=2^r.

Usage

createBoseBush(q, ncol, bRandom = TRUE)

Arguments

q the number of symbols in the array
ncol number of parameters or columns
bRandom should the array be randomized

Details

From Owen: An orthogonal array A is a matrix of n rows, k columns with every element being one of q symbols 0, . . . , q-1. The array has strength t if, in every n by t submatrix, the q^t possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted lambda. Clearly, lambda*q^t=n. The notation for such an array is OA( n,k,q,t ).

Value

an orthogonal array

References

Owen, Art. Orthogonal Arrays for: Computer Experiments, Visualizations, and Integration in high
createBoseBushl

Create an orthogonal array using the Bose-Bush algorithm with alternate strength >= 3.

Description

The bosebushl program produces OA( lambda*q^2, k, q, 2 ), k <= lambda*q*1, for prime powers q and lambda > 1. Both q and lambda must be powers of the same prime.

Usage

createBoseBushl(q, ncol, lambda, bRandom = TRUE)

Arguments

- q: the number of symbols in the array
- ncol: number of parameters or columns
- lambda: the lambda of the BoseBush algorithm
- bRandom: should the array be randomized

Details

From Owen: An orthogonal array A is a matrix of n rows, k columns with every element being one of q symbols 0, ..., q-1. The array has strength t if, in every n by t submatrix, the q^t possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted lambda. Clearly, lambda*q^t=n. The notation for such an array is OA( n, k, q, t ).

Value

an orthogonal array

Examples

```r
A <- createBoseBushl(3, 3, 3, TRUE)
B <- createBoseBushl(4, 4, 16, TRUE)
```

createBush

Create an orthogonal array using the Bush algorithm.

Description

The bush program produces \( \text{OA}(q^3, k, q, 3) \), \( k \leq q+1 \) for prime powers \( q \).

Usage

```r
createBush(q, ncol, bRandom = TRUE)
```

Arguments

- `q` the number of symbols in the array
- `ncol` number of parameters or columns
- `bRandom` should the array be randomized

Details

From Owen: An orthogonal array \( A \) is a matrix of \( n \) rows, \( k \) columns with every element being one of \( q \) symbols \( 0, \ldots, q-1 \). The array has strength \( t \) if, in every \( n \) by \( t \) submatrix, the \( q^t \) possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted \( \lambda \). Clearly, \( \lambda q^t = n \). The notation for such an array is \( \text{OA}(n, k, q, t) \).

Value

an orthogonal array

Examples

```r
A <- createBush(3, 3, FALSE)
B <- createBush(4, 5, TRUE)
```

createBusht

Create an orthogonal array using the Bush algorithm with alternate strength.

Description

The `busht` program produces $\text{OA}(q^t, k, q, t)$, $k \leq q+1$, $t \geq 3$, for prime powers $q$.

Usage

```r
createBusht(q, ncol, strength, bRandom = TRUE)
```

Arguments

- `q` the number of symbols in the array
- `ncol` number of parameters or columns
- `strength` the strength of the array to be created
- `bRandom` should the array be randomized

Details

From Owen: An orthogonal array $A$ is a matrix of $n$ rows, $k$ columns with every element being one of $q$ symbols 0, ..., $q-1$. The array has strength $t$ if, in every $n$ by $t$ submatrix, the $q^t$ possible distinct rows, all appear the same number of times. This number is the index of the array, commonly denoted $\lambda$. Clearly, $\lambda q^t = n$. The notation for such an array is $\text{OA}(n, k, q, t)$.

Create an orthogonal array Latin hypercube

Description

Create an orthogonal array Latin hypercube

Usage

create_oalhs(n, k, bChooseLargerDesign, bverbose)

Arguments

n 
the number of samples or rows in the LHS (integer)

k 
the number of parameters or columns in the LHS (integer)

bChooseLargerDesign 
should a larger oa design be chosen than the n and k requested?

bverbose 
should information be printed with execution

Value

a numeric matrix which is an orthogonal array Latin hypercube sample

Examples

set.seed(34)
A <- create_oalhs(9, 4, TRUE, FALSE)
B <- create_oalhs(9, 4, TRUE, FALSE)
## Description

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function attempts to optimize the sample with respect to the S optimality criterion through a genetic type algorithm.

## Usage

```r
geneticLHS(
  n = 10,
  k = 2,
  pop = 100,
  gen = 4,
  pMut = 0.1,
  criterium = "S",
  verbose = FALSE
)
```

## Arguments

- **n**: The number of partitions (simulations or design points or rows)
- **k**: The number of replications (variables or columns)
- **pop**: The number of designs in the initial population
- **gen**: The number of generations over which the algorithm is applied
- **pMut**: The probability with which a mutation occurs in a column of the progeny
- **criterium**: The optimality criterion of the algorithm. Default is "S". Maximin is also supported
- **verbose**: Print informational messages. Default is FALSE

## Details

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square iff there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of \(k\) variables, the range of each variable is divided into \(n\) equally probable intervals. \(n\) sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first \(n\) integers in each of \(k\) columns and then transforming those integers into \(n\) sections of a standard uniform distribution. Random values are then sampled from within each of the \(n\) sections. Once the
sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g. `qnorm()`. Different columns can have different distributions.

S-optimality seeks to maximize the mean distance from each design point to all the other points in the design, so the points are as spread out as possible.

Genetic Algorithm:

1. Generate `pop` random latin hypercube designs of size `n` by `k`
2. Calculate the S optimality measure of each design
3. Keep the best design in the first position and throw away half of the rest of the population
4. Take a random column out of the best matrix and place it in a random column of each of the other matrices, and take a random column out of each of the other matrices and put it in copies of the best matrix thereby causing the progeny
5. For each of the progeny, cause a genetic mutation `pMut` percent of the time. The mutation is accomplished by switching two elements in a column

Value

An `n` by `k` Latin Hypercube Sample matrix with values uniformly distributed on [0,1]

A <- geneticLHS(4, 3, 50, 5, .25)
```
improvedLHS  

**Improved Latin Hypercube Sample**

**Description**

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function attempts to optimize the sample with respect to an optimum euclidean distance between design points.

**Usage**

```r
improvedLHS(n, k, dup = 1)
```

**Arguments**

- `n` The number of partitions (simulations or design points or rows)
- `k` The number of replications (variables or columns)
- `dup` A factor that determines the number of candidate points used in the search. A multiple of the number of remaining points than can be added.

**Details**

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square iff there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of `k` variables, the range of each variable is divided into `n` equally probable intervals. `n` sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first `n` integers in each of `k` columns and then transforming those integers into `n` sections of a standard uniform distribution. Random values are then sampled from within each of the `n` sections. Once the sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g. `qnorm()`. Different columns can have different distributions.

This function attempts to optimize the sample with respect to an optimum euclidean distance between design points.

\[
Optimum\text{distance} = \frac{1}{n^k}
\]

**Value**

An `n` by `k` Latin Hypercube Sample matrix with values uniformly distributed on [0,1]
References

This function is based on the MATLAB program written by John Burkardt and modified 16 Feb 2005 https://people.sc.fsu.edu/~jburkardt/m_src/ihs/ihs.m

See Also

[randomLHS()], [geneticLHS()], [maximinLHS()], and [optimumLHS()] to generate Latin Hypercube Samples. [optAugmentLHS()], [optSeededLHS()], and [augmentLHS()] to modify and augment existing designs.

Examples

```r
set.seed(1234)
A <- improvedLHS(4, 3, 2)
```

maximinLHS

Maximin Latin Hypercube Sample

Description

 Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function attempts to optimize the sample by maximizing the minimum distance between design points (maximin criteria).

Usage

```r
maximinLHS(
  n,
  k,
  method = "build",
  dup = 1,
  eps = 0.05,
  maxIter = 100,
  optimize.on = "grid",
  debug = FALSE
)
```

Arguments

- `n` The number of partitions (simulations or design points or rows)
- `k` The number of replications (variables or columns)
- `method` build or iterative is the method of LHS creation. build finds the next best point while constructing the LHS. iterative optimizes the resulting sample on [0,1] or sample grid on [1,N]
maximinLHS

dup  A factor that determines the number of candidate points used in the search. A multiple of the number of remaining points than can be added. This is used when method="build"
eps  The minimum percent change in the minimum distance used in the iterative method
maxIter  The maximum number of iterations to use in the iterative method
optimize.on  grid or result gives the basis of the optimization. grid optimizes the LHS on the underlying integer grid. result optimizes the resulting sample on [0,1]
debug  prints additional information about the process of the optimization

Details

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square iff there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of $k$ variables, the range of each variable is divided into $n$ equally probable intervals. $n$ sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first $n$ integers in each of $k$ columns and then transforming those integers into $n$ sections of a standard uniform distribution. Random values are then sampled from within each of the $n$ sections. Once the sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g. qnorm(). Different columns can have different distributions.

Here, values are added to the design one by one such that the maximin criteria is satisfied.

Value

An $n \times k$ Latin Hypercube Sample matrix with values uniformly distributed on [0,1]

References

This function is motivated by the MATLAB program written by John Burkardt and modified 16 Feb 2005 https://people.sc.fsu.edu/~jburkardt/m_src/ihs/ihs.m

**oa_to_oalhs**  
*Create a Latin hypercube from an orthogonal array*

**Description**
Create a Latin hypercube from an orthogonal array

**Usage**
oa_to_oalhs(n, k, oa)

**Arguments**
- `n`: the number of samples or rows in the LHS (integer)
- `k`: the number of parameters or columns in the LHS (integer)
- `oa`: the orthogonal array to be used as the basis for the LHS (matrix of integers) or data.frame of factors

**Value**
a numeric matrix which is a Latin hypercube sample

**Examples**
oa <- createBose(3, 4, TRUE)
B <- oa_to_oalhs(9, 4, oa)

---

**optAugmentLHS**  
*Optimal Augmented Latin Hypercube Sample*

**Description**
Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the *latin* properties of the design. This function attempts to add the points to the design in an optimal way.

**Usage**
optAugmentLHS(lhs, m = 1, mult = 2)
Arguments

1hs  The Latin Hypercube Design to which points are to be added
m   The number of additional points to add to matrix 1hs
mult m*mult random candidate points will be created.

Details

Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the latin properties of the design. This function attempts to add the points to the design in a way that maximizes S optimality.

S-optimality seeks to maximize the mean distance from each design point to all the other points in the design, so the points are as spread out as possible.

Value

An n by k Latin Hypercube Sample matrix with values uniformly distributed on [0,1]

References

a <- randomLHS(4,3)
b <- optAugmentLHS(a, 2, 3)
```

optimumLHS

Optimum Latin Hypercube Sample

Description

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function uses the Columnwise Pairwise (CP) algorithm to generate an optimal design with respect to the S optimality criterion.

Usage

```r
optimumLHS(n = 10, k = 2, maxSweeps = 2, eps = 0.1, verbose = FALSE)
```
optimumLHS

Arguments

n      The number of partitions (simulations or design points or rows)
k      The number of replications (variables or columns)
maxSweeps  The maximum number of times the CP algorithm is applied to all the columns.
eps           The optimal stopping criterion. Algorithm stops when the change in optimality
                      measure is less than eps*100% of the previous value.
verbose  Print informational messages

Details

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square iff there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of \( k \) variables, the range of each variable is divided into \( n \) equally probable intervals. \( n \) sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first \( n \) integers in each of \( k \) columns and then transforming those integers into \( n \) sections of a standard uniform distribution. Random values are then sampled from within each of the \( n \) sections. Once the sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g. qnorm(). Different columns can have different distributions.

S-optimality seeks to maximize the mean distance from each design point to all the other points in the design, so the points are as spread out as possible.

This function uses the \( CP \) algorithm to generate an optimal design with respect to the S optimality criterion.

Value

An \( n \) by \( k \) Latin Hypercube Sample matrix with values uniformly distributed on \([0,1]\)

References

Examples

A <- optimumLHS(4, 3, 5, .05)
optSeededLHS

Optimum Seeded Latin Hypercube Sample

Description
Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the latin properties of the design. This function then uses the columnwise pairwise (CP) algorithm to optimize the design. The original design is not necessarily maintained.

Usage
optSeededLHS(seed, m = 0, maxSweeps = 2, eps = 0.1, verbose = FALSE)

Arguments
- **seed**: The number of partitions (simulations or design points)
- **m**: The number of additional points to add to the seed matrix seed. default value is zero. If m is zero then the seed design is optimized.
- **maxSweeps**: The maximum number of times the CP algorithm is applied to all the columns.
- **eps**: The optimal stopping criterion
- **verbose**: Print informational messages

Details
Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the latin properties of the design. This function then uses the CP algorithm to optimize the design. The original design is not necessarily maintained.

Value
An n by k Latin Hypercube Sample matrix with values uniformly distributed on [0,1]

References

a <- randomLHS(4, 3)
b <- optSeededLHS(a, 2, 2, .1)
```
Construct a random Latin hypercube design

Description

randomLHS(4, 3) returns a 4x3 matrix with each column constructed as follows: A random permutation of (1,2,3,4) is generated, say (3,1,2,4) for each of K columns. Then a uniform random number is picked from each indicated quartile. In this example a random number between .5 and .75 is chosen, then one between 0 and .25, then one between .25 and .5, finally one between .75 and 1.

Usage

randomLHS(n, k, preserveDraw = FALSE)

Arguments

n the number of rows or samples
k the number of columns or parameters/variables
preserveDraw should the draw be constructed so that it is the same for variable numbers of columns?

Value

a Latin hypercube sample

Examples

a <- randomLHS(5, 3)

Create a Random Sample of Uniform Integers

Description

Create a Random Sample of Uniform Integers

Usage

runifint(n = 1, min_int = 0, max_int = 1)

Arguments

n The number of samples
min_int the minimum integer $x \geq min_int$
max_int the maximum integer $x \leq max_int$
Value

the sample sample of size n
